Molecular characteristics: Our phylogenetic analyses support the designation of *Me. azagnyi* as a new species. Genetic distances between *Me. azagnyi* and its sister species, *Me. woermanni* were 4.9 - 5.7% with Cytb sequences (n = 41; 1140 nt), and 0.3 - 0.4% with the nuclear dataset (n = 6; 5415 nt).

Molecular phylogenetics is the branch of phylogeny that analyzes genetic, hereditary molecular differences, predominately in DNA sequences, to gain information on an organism's evolutionary relationships. From these analyses, it is possible to determine the processes by which diversity among species has been achieved. The result of a molecular phylogenetic analysis is expressed in a phylogenetic tree. Molecular phylogenetics is one aspect of molecular systematics, a broader term that also includes

Phylogeography deals with historical phylogenetic components of the geographic distributions of genealogical lineages, particularly those within and among closely associated species (Avice, 2000). Intraspecific phylogeographical patterns usually arise from biogeographic barriers to gene flow like vicariance and

Abstract. Flow cytometry, morphometry and molecular markers [plastid DNA and internal transcribed spacers (ITS) of nuclear ribosomal DNA] were used to determine taxonomic and phylogeographic patterns in *Dactylorhiza maculata* s.l. from Scandinavia. A total of 238 individuals from 27 populations from throughout all of Scandinavia, including the adjacent Kola Peninsula of Russia, were analyzed.
